Morbidity and Mortality Weekly Report

Weekly March 9, 2007 / Vol. 56 / No. 9

Racial/Ethnic Disparities in Diagnoses of HIV/AIDS — 33 States, 2001–2005

During 2001–2004, blacks* accounted for 51% of newly diagnosed human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) infections in the United States (*1*). This report updates HIV/AIDS diagnoses during 2001–2005 among black adults and adolescents and other racial/ethnic populations reported to CDC through June 2006 by 33 states† that had used confidential, name-based reporting of HIV and AIDS cases since at least 2001. Of the estimated 184,991 adult and adolescent HIV infections diagnosed during 2001–2005, more (51%) occurred among blacks than among all other racial/ethnic populations combined. Most (62%) new HIV/AIDS diagnoses were among persons aged 25–44 years; in this age group, blacks accounted for 48% of new HIV/AIDS diagnoses. New interventions and mobilization of the broader community are needed to reduce the disproportionate impact of HIV/AIDS on blacks in the United States.

For this report, cases of HIV or AIDS were analyzed together as HIV/AIDS (i.e., HIV infection with or without AIDS) and counted by year of diagnosis. Cases were classified according to the following transmission categories: 1) male-to-male sexual contact (i.e., among men who have sex with men [MSM]); 2) injection-drug use (IDU); 3) MSM with IDU; 4) high-risk heterosexual contact (i.e., with a person of the opposite sex known to be HIV infected or at high risk for HIV/AIDS [e.g., MSM or injection-drug user]); and 5) other (e.g., hemophilia or blood transfusion) and all risk factors not reported or not identified. The estimated number of HIV/AIDS diagnoses for each racial/ethnic population by transmission category and selected characteristic was calculated. For 2005, estimated diagnosis rates per 100,000 population were calculated for each racial/ethnic population, and rate ratios (RRs) comparing other populations with whites were determined. In addition, estimated HIV§ prevalence and AIDS¶ prevalence rates for blacks living with HIV or AIDS at the end of 2005 were calculated. Prevalence estimates were derived from reported cases and adjusted for delays in reporting and deaths (*2*).** Estimated HIV and AIDS prevalence rates per 100,000 population were calculated for each state and the District of Columbia (DC).

* For this report, persons identified as white, black, Asian/Pacific Islander, American Indian/Alaska Native, or of other/unknown race are all non-Hispanic. Persons identified as Hispanic might be of any race.

† Alabama, Alaska, Arizona, Arkansas, Colorado, Florida, Idaho, Indiana, Iowa, Kansas, Louisiana, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, South Carolina, South Dakota, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, and Wyoming.

§ Includes only persons living with HIV that had not progressed to AIDS. These data were reported by the 33 U.S. states with confidential, name-based HIV reporting since at least 2001. Because HIV can be diagnosed at any time in the disease spectrum, the time between HIV and AIDS diagnoses varies.

¶ Includes only persons living with AIDS. Cases were from the 50 U.S. states and the District of Columbia (DC). Because DC is not a state, caution should be exercised when comparing DC AIDS rates with those of the states.

** Reporting delays (i.e., time between diagnosis and report) can differ by geographic location, age, sex, transmission category, and racial/ethnic population. Adjustments for reporting time were calculated for HIV and AIDS cases using a maximum likelihood statistical procedure that accounts for differences in reporting time for the preceding characteristics while assuming the reporting delay has remained constant over time. Adjustments also were made for cases initially reported without transmission category information. Adjustments for adults and adolescents were based on the redistribution of cases across transmission categories by sex, race/ethnicity, and geographic region for cases diagnosed 3–10 years earlier and initially classified as reported without risk factor information but later reclassified.

Although adult and adolescent blacks accounted for 13% of the population in the 33 states during 2001–2005 (*3*), they accounted for 50.5% of the 184,991 new HIV/AIDS diagnoses; whites accounted for 72% of the population and 29.3% of diagnoses, and Hispanics accounted for 13% of the population and 18.2% of diagnoses. Among racial/ethnic populations, blacks accounted for the largest percentages of cases diagnosed in both males (43.9%) and females (67.2%) (Table 1).

During 2001–2005, blacks had the largest percentage of HIV/AIDS diagnoses in all age groups and in the IDU and high-risk heterosexual transmission categories (Table 1). Among men and women with IDU and persons with high-risk heterosexual contact, more than half were black (men: 53.8% and 65.7%, respectively; women: 58.8% and 69.5%, respectively). More MSM with HIV/AIDS diagnoses were white (42.7%), with smaller proportions of blacks (36.2%) and Hispanics (19.0%).

During 2001–2005, adults aged 25–44 years accounted for a majority of HIV/AIDS diagnoses regardless of racial/ethnic population (Table 1). Among persons aged 25–34 and 35–44 years, blacks accounted for the greatest proportion of cases (48.0% and 47.5%, respectively). By region,[††] blacks accounted for the majority of diagnoses in the South (54.3%) and Northeast (52.0%) (Table 1). Black males accounted for more new HIV/AIDS diagnoses than males of any other racial/ethnic population in the South (47.5%) and Northeast (46.1%). Among females, blacks accounted for the majority of HIV/AIDS diagnoses in the South (71.5%), Northeast (64.4%), and Midwest (63.5%), compared with other racial/ethnic populations.

Among black males and females, the age distribution of persons who had HIV/AIDS diagnosed varied by transmission category (Table 2). By transmission category, most HIV/AIDS diagnoses of black male adults and adolescents were classified as MSM (30,154 [51.7%]), followed by high-risk heterosexual contact (14,698 [25.2%]), IDU (10,415 [17.9%]), MSM with IDU (2,698 [4.6%]), and other (322 [0.6%]). Most HIV/AIDS diagnoses among black female adults and adolescents were classified as high-risk heterosexual contact (28,283 [80.4%]), followed by IDU (6,412 [18.2%]), and other (465 [1.3%]) (Table 2).

In 2005, the estimated annual HIV/AIDS diagnosis rate among black males was 127.6 per 100,000 population and among black females was 61.4 per 100,000, both higher than

[††] *Northeast*: New Jersey and New York. *Midwest*: Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. *South*: Alabama, Arkansas, Florida, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia. *West*: Alaska, Arizona, Colorado, Idaho, Nevada, New Mexico, Utah, and Wyoming.

TABLE 1. Estimated number and percentage of HIV/AIDS* diagnoses among adults and adolescents, by race/ethnicity and selected characteristics — 33 states, 2001–2005†

* Includes persons diagnosed with HIV infection with or without AIDS.

† Data as of June 2006, adjusted for reporting delays and risk factor redistribution.

§ Because subpopulation values were calculated independently, the values might not sum to the row total.

¶ Diagnoses were classified in the following hierarchy of transmission categories: 1) male-to-male sexual contact (i.e., among men who have sex with men [MSM]); 2) injection-drug use (IDU); 3) MSM with IDU; 4) high-risk heterosexual contact (i.e., with a person of the opposite sex known to be HIV infected or at high risk for HIV/AIDS [e.g., MSM or injection-drug user]); and 5) other (e.g., hemophilia or blood transfusion) and all risk factors not reported or not identified.

** *Northeast*: New Jersey and New York. *Midwest*: Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. *South*: Alabama, Arkansas, Florida, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia. *West*: Alaska, Arizona, Colorado, Idaho, Nevada, New Mexico, Utah, and Wyoming.

the rates for all other racial/ethnic populations. Among males, the annual HIV/AIDS diagnosis black/white RR of 6.9 was higher than the Hispanic/white RR of 3.1. Among females, the black/white RR was 20.5, and the Hispanic/white RR was 5.4.

In 2005, overall estimated HIV (i.e., without AIDS) and AIDS prevalences were higher among blacks than among all other racial/ethnic populations. Among blacks, the estimated HIV prevalence (in 33 states) was 515 per 100,000 population, ranging from 109 (Alaska) to 858 (New Jersey); the estimated AIDS prevalence (in the 50 states and DC) was 639 per 100,000 population and ranged from 79 (Wyoming) to 3,179 (DC) (Table 3).

Reported by: *T Durant, PhD, K McDavid, PhD, X Hu, MS, P Sullivan, DVM, PhD, R Janssen, MD, Div of HIV/AIDS Prevention; K Fenton, MD, PhD, Office of the Director, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention (proposed), CDC.*

Editorial Note: During 2001–2005, HIV/AIDS diagnoses, diagnosis rates, and RRs were higher among black males and females than among any other racial/ethnic population in the United States. In 2005, the annual rates of HIV/AIDS diagnosis among black men and women were seven and 21 times higher than rates among white men and women, respectively. For black men, sexual contact with men was the primary mode of HIV infection; for black women, high-risk heterosexual

* Includes persons diagnosed with HIV infection with or without AIDS.
† Data as of June 2006, adjusted for reporting delays and risk factor redistribution.
§ Diagnoses were classified in the following hierarchy of transmission categories: 1) male-to-male sexual contact (i.e., among men who have sex with men [MSM]); 2) injection-drug use (IDU); 3) MSM with IDU; 4) high-risk heterosexual contact (i.e., with a person of the opposite sex known to be HIV infected or at high risk for HIV/AIDS [e.g., MSM or injection-drug user]); and 5) other (e.g., hemophilia or blood transfusion) and all risk factors not reported or not identified.
¶ Because subpopulation values were calculated independently, the values might not sum to the row total.

contact was the primary mode. In a recent study of MSM in five cities, 46% of blacks were infected with HIV, compared with 21% of whites and 17% of Hispanics (*4*). In 2004, HIV/AIDS was the fourth-leading cause of death among blacks aged 25–44 years in the United States (*5*).

During 2001–2004, HIV diagnosis rates among black males and females declined by 4.4% and 6.8%, respectively (*1*). A 2007 study reported similar declines among blacks in Florida (*6*). These declines were observed among black heterosexuals and injection-drug users but not among MSM. Although these declines in rates of new HIV diagnoses are encouraging, they might not directly reflect trends in HIV incidence because they are also affected by changes in testing behavior and surveillance practices. Regardless of the trends, blacks remain disproportionately affected by high rates of HIV/AIDS. Several factors might contribute to these higher rates (e.g., higher overall prevalence of infection and undiagnosed infection among MSM or greater likelihood among females of high-risk heterosexual contact) (*7*).

The findings in this report are subject to at least two limitations. First, the data were reported from states with confidential, name-based HIV/AIDS surveillance systems and are not necessarily representative of all persons in the United States testing positive for HIV. Diagnoses of HIV/AIDS from areas with historically high AIDS morbidity that do not conduct confidential, name-based surveillance (e.g., California, Illinois, and DC) were not included. However, the racial/ethnic disparities described in this report are similar to disparities observed among persons with AIDS from all 50 states (*8*). Second, the findings might be affected by statistical adjustments made for reporting delays and for cases reported with no identified risk factor. Such cases were reclassified based on data obtained from follow-up investigations and were assumed to constitute a representative sample of all cases initially reported without a risk factor. However, this assumption might not be valid, potentially affecting the accuracy of the estimated distribution of cases by transmission category.

The high rate of infection among blacks highlights the need to scale up known, effective HIV-prevention interventions and to implement new, improved, and culturally appropriate HIV/AIDS strategies. CDC, along with public health partners and community leaders, is announcing its Heightened National Response to the HIV/AIDS Crisis among African Americans to reduce the toll of this disease. This response will focus on four main areas: 1) expanding the reach of prevention services, including ensuring that federal prevention resources are expended where the need is greatest; 2) increasing opportunities for diagnosing and treating HIV, including encouraging more blacks to know their HIV serostatus; 3) developing new, effective, prevention interventions, including behavioral, social, and structural interventions; and 4) mobilizing broader action within communities to help change community perceptions about HIV/AIDS, to motivate blacks to seek early HIV diagnosis and treatment, and to encourage healthy behaviors and community norms that prevent the spread of HIV.

CDC will expand its partnerships with other federal agencies, state and local health departments, academic institutions, and community-based organizations to enhance research, policy, prevention services, testing, and linkage to care for blacks. CDC and public health partners will work with black faith, entertainment, media, civic, education, and business leaders and others who have not been historically involved in HIV prevention to address community awareness, perceptions,

Influenza Vaccination Coverage Among Children with Asthma — United States, 2004–05 Influenza Season

In 2005, approximately 8.9% (6.5 million) of U.S. children aged <18 years were reported to have current asthma (*1*). Children with asthma are at high risk for complications from influenza, and influenza vaccination has been determined to safely and effectively reduce rates of influenza in these children (*2*). Since its establishment in 1964, the Advisory Committee on Immunization Practices (ACIP) has recommended that all children with asthma aged ≥6 months receive vaccination with inactivated influenza vaccine during each influenza season; however, national influenza vaccination coverage rates specifically for children with asthma have not been determined (*2*). Previous studies have assessed influenza vaccination rates in children with asthma at the local level using health maintenance organization and clinician group-practice

information, with estimates ranging from 10% to 43% for various influenza seasons (*3,4*). Another study used Behavioral Risk Factor Surveillance System (BRFSS) data to estimate influenza vaccination coverage in children aged 2–17 years with one or more conditions putting them at high risk for complications from influenza (including asthma, although asthma was not assessed separately); in that study, the national rate was estimated at 34.8% for the 2004–05 influenza season (based on a sample size of 685, which included all states and the District of Columbia [DC]) (*5*). To estimate national influenza vaccination coverage rates among children aged 2–17 years with current asthma,* CDC analyzed data from the 2005 National Health Interview Survey (NHIS). This report describes the results of that analysis and provides the first national estimates of influenza vaccination coverage among children with asthma. The findings indicated that although children with current asthma were more likely to receive influenza vaccination than children without current asthma, the vaccination coverage rate among children with asthma was low, at 29.0% (95% confidence interval [CI] = 24.5–33.9). These findings underscore the need to increase influenza vaccination coverage in children with asthma aged 2–17 years by identifying and overcoming barriers to vaccination.

NHIS is an ongoing, cross-sectional, in-person household interview survey of the civilian, noninstitutionalized population of the United States. During the interview, information about one randomly selected child from each family is collected from an adult family member who resides in the same household as the child. The child questionnaire contains several questions that assess asthma status; in 2005, NHIS added questions regarding influenza vaccination for children. Because NHIS interviews are conducted throughout the year, the 2005 questions regarding receipt of influenza vaccination during the 12 months preceding the interview could have elicited responses that referred to vaccination that occurred during the end of the 2003–04 influenza season, the entire 2004–05 season, or the beginning of the 2005–06 season. In addition, participants who were questioned during the 2004–05 influenza season could have reported no influenza vaccination at the time of the survey but then received one later during the same season. To address these methodological concerns and attempt to ensure that the responses included in this analysis were only in reference to the 2004–05 influenza season (September 2004–February 2005), only responses from interviews conducted during March–August 2005 were included in the analysis. Using this methodology, future NHIS data can be analyzed for influenza vaccination coverage by influenza season.

In this study, NHIS data from 2005 were used to estimate influenza vaccination coverage during the 2004–05 influenza season for children aged 2–17 years† by asthma status and age group. Coverage also was estimated by asthma status and reported number of visits to a health-care provider in the preceding 12 months.

A total of 5,124 children aged 2–17 years were included in the analysis by age group, and 5,097 children were included in the analysis by number of health-care visits. Only children who were aged 2–17 years for the entire 2004–05 influenza season were included. A child was considered vaccinated for the 2004–05 influenza season if the child had a reported date of vaccination during September 2004–February 2005. Of the children in the sample with a reported influenza vaccination in the preceding 12 months, 7.9% were excluded from the analysis for not reporting a date of vaccination. In addition, 7.8% of those with a reported influenza vaccination in the preceding 12 months were not included because their reported date of vaccination did not occur during September 2004–February 2005 (i.e., reported vaccination occurred during months in which the influenza vaccine was likely unavailable). Univariate analysis was performed, and samples were weighted to produce national estimates.

Influenza vaccination coverage for the 2004–05 influenza season among children aged 2–17 years was 29.0% for children with current asthma and 10.3% for children without current asthma. Children with current asthma had similar rates of vaccination among all age groups, ranging from 32.9% to 28.0% among children aged 2–4 years and 5–12 years, respectively. In contrast, children without current asthma had a wider variation in vaccination coverage by age group, with younger children having higher rates of vaccination than older children (20.7% for ages 2–4 years versus 6.4% for ages 13–17 years, $p<0.001$ by *t* test) (Table 1). Calculation of influenza vaccination-coverage rates in children with current asthma who had experienced an asthma attack or episode during the 12 months preceding the interview indicated that these children had higher coverage rates than those without an attack or episode (35.9% versus 20.0%, $p<0.001$, by chi-square test). The lowest vaccination rate among children with current asthma (16.4%) was

* *Current asthma:* "Yes" response to the survey question, "Has a doctor or other health professional ever told you that [child] had asthma?" and a "yes" response to the survey question, "Does [child] still have asthma?" *Without current asthma:* "No" response to the survey question, "Has a doctor or other health professional ever told you that [child] had asthma?" or a "no" response to the survey question, "Does [child] still have asthma?" *Asthma attack or episode:* "Yes" response to the survey question, "During the past 12 months, has [child] had an episode of asthma or an asthma attack?"

† Children aged <2 years were not included because 1) asthma diagnoses are considered unreliable in children at this age, 2) the 2004–05 influenza recommendations called for vaccination of all children aged 6–23 months regardless of asthma status (therefore, ages 2–17 years were the only ages with influenza vaccination recommendations specific to children with asthma), and 3) previous BRFSS studies used an age range of 2–17 years.

for children aged 5–12 years who had not had an asthma attack or episode in the 12 months preceding the interview.

Among children with the same number of health-care visits during the 12 months preceding the interview, children with asthma who had two through five or ≥10 health-care visits had higher rates of influenza vaccination than children without asthma (Table 2). In addition, influenza vaccination coverage among children with current asthma increased as the reported number of health-care visits increased. Approximately 10.8% of children with current asthma who had one health-care visit in the preceding year were vaccinated, whereas 42.0% of children with current asthma who had ≥10 visits were vaccinated.

Reported by: *SN Brim, MA, RA Rudd, MSPH, RH Funk, DVM, DB Callahan, MD, Div of Environmental Hazards and Health Effects, National Center for Environmental Health; GL Euler, DrPH, Immunization Svcs Div, National Center for Immunization and Respiratory Diseases (proposed), CDC.*

Editorial Note: The findings in this report, based on 2005 NHIS data, include the first national estimate of influenza vaccination coverage in children with current asthma. The analysis indicated a lower coverage rate (29.0%) during the 2004–05 influenza season than a previous study based on BRFSS data (34.8%) that included children with conditions placing them at high risk for influenza complications (*5*). Because BRFSS and NHIS have different survey methodologies, a difference was not unexpected. The BRFSS analysis included children with conditions other than asthma, including other lung problems, heart problems, diabetes, kidney

§§ Estimate is unreliable (relative standard error >0.3).

problems, a weakened immune system, anemia, or aspirin therapy for chronic conditions. In addition, this study based on NHIS data used September–February as its time frame for influenza vaccination, whereas the BRFSS study used September–January. Finally, BRFSS is conducted in all states and DC, whereas NHIS uses a sampling method designed to produce an accurate national estimate without including all states.

An unexpected influenza vaccine shortage occurred during the 2004–05 influenza season. In October 2004, within days of the first indication of the shortage, CDC released interim recommendations for prioritizing influenza vaccine distribution. Children aged 2–17 years with asthma were included in the priority group of "persons aged 2–64 years with underlying chronic conditions" (*6*). This interim recommendation might have contributed to the higher influenza vaccination rates for children with asthma compared with children without asthma as clinicians followed recommendations; alternatively, the shortage might have led to an overall decrease in coverage rates among all children, including children with asthma, compared with rates from other seasons. The results of this analysis cannot be compared with previous years because 2005 was the first year that NHIS included influenza vaccination questions on the child portion of the survey. Analysis of NHIS data from 2006 and future years will allow determination of trends in national influenza vaccination coverage in children with asthma.

The differing coverage rates, by age, among children without current asthma likely are a result of various factors. For example, the high rate of vaccination in children aged 2–4 years compared with other ages might be a reflection of the regularly scheduled pediatric well-child visits for young children, which might result in receipt of an influenza vaccination. In addition, physician awareness of the increased risk for influenza complications in children aged 2–4 years might have contributed to this higher vaccination rate.

The findings in this report are subject to at least three limitations. First, the results might be affected by recall bias, which might cause underreporting of vaccination directly proportional to the time between vaccination and interview. However, if parents of children with asthma preferentially recall influenza vaccination, this would contribute to higher coverage estimates for children with asthma compared with children without asthma. Second, inaccurate reporting of vaccination dates might cause misclassification of responses during the analysis; NHIS responses for children are based on report by an adult and are not confirmed by health-care providers. Finally, whether children aged ≤9 years who were receiving their first influenza vaccination also received the second dose recommended by ACIP for maximum protection could not be determined on the basis of NHIS data (*2*).

In February 2006, ACIP expanded its influenza vaccination recommendation to include all children aged 6–59 months, and the committee also is evaluating a universal influenza vaccination strategy (*7*). Continued monitoring of influenza vaccination coverage among children with asthma in future influenza seasons is needed to determine how these recommendations affect coverage rates in this population.

The findings in this analysis indicate that influenza vaccination coverage among children with asthma is inadequate and that opportunities for vaccination during health-care provider visits likely are being missed. Previous studies have assessed methods to improve influenza vaccination rates, such as year-round scheduling of fall and winter influenza vaccination appointments and computerized reminder systems (*8,9*). In one study, the percentage of children with asthma who received at least 1 dose of influenza vaccine increased from 23.2% to 35.1% ($p<0.001$) after implementation of a year-round scheduling policy (*8*).

National trends in coverage should be monitored so that public health policies can better target vaccination of all children with asthma, and correlates of vaccination among children with asthma should be explored so that measures can be developed for groups of children with asthma who have the lowest rates of vaccination. Increasing influenza vaccination coverage in this population will help decrease influenza and its associated complications.

Invasive Methicillin-Resistant *Staphylococcus aureus* Infections Among Dialysis Patients — United States, 2005

Staphylococcus aureus is a leading cause of bloodstream and other invasive infections in the United States. *S. aureus* has become increasingly resistant to first-line antimicrobial agents in health-care settings (*1*). Dialysis patients are especially vulnerable to infections, frequently those caused by antimicrobial-resistant organisms, including methicillin-resistant *Staphylococcus aureus* (MRSA). To assess the incidence of invasive MRSA infection among dialysis patients in the United States during 2005, surveillance data were analyzed from the Active Bacterial Core surveillance (ABCs) system. This report summarizes the results of that analysis, which estimated that, in 2005, the incidence of invasive MRSA infection among dialysis patients was 45.2 cases per 1,000 population. Persons receiving dialysis are at high risk for infection with invasive MRSA compared with the general population, in which rates of invasive MRSA have ranged from 0.2 to 0.4 infections per 1,000 population (*2*). The findings in this report underscore the need for continued surveillance and infection-control strategies aimed at reducing infection rates and preventing additional antimicrobial resistance among persons receiving dialysis.

ABCs, part of CDC's Emerging Infections Program, conducts ongoing, active, population-based surveillance for invasive pathogens, including MRSA, in selected areas of the United States. In 2005, the entire state of Connecticut and 23 counties in eight other states (California, Colorado, Georgia, Maryland, Minnesota, New York, Oregon, and Tennessee) monitored MRSA infections. A case was defined as a positive MRSA culture from normally sterile sites (e.g., blood, cerebrospinal fluid, joint fluid, or pleural fluid) occurring in a patient residing in the ABCs surveillance area. Surveillance staff collected demographic and clinical data from patient records and reported the data to CDC. All cases of invasive MRSA reported during 2005 were used to calculate incidence rates. Demographic and outcome data were analyzed from case reports obtained during July 2004–June 2006. The analysis was limited to cases occurring in patients with a history of peritoneal dialysis or hemodialysis during the preceding 12 months; recurrent cases were excluded. The number of dialysis patients was obtained for Connecticut and the 23 counties from the United States Renal Data System dialysis population count (as of December 31, 2004) for use as denominators; 2005 denominators were not yet available (*3*).

Laboratories voluntarily submitted isolates from cases, and a subset of isolates was collected for microbiologic characterization at CDC. A total of 126 isolates were obtained from dialysis patients. Isolates were tested by pulsed-field gel electrophoresis (PFGE) and were grouped into types using Dice coefficients with 80% relatedness. Isolates with pulsed-field types USA300, USA400, USA1000, or USA1100 are obtained primarily from community infections and are considered to be of community origin; those with types USA100, USA200, and USA500 are predominantly from health-care–associated infections and are considered to be of health-care origin (*4*).

Of the 5,287 cases of invasive MRSA reported from ABCs sites during 2005, a total of 813 (15.4%) occurred in dialysis patients. Overall incidence of invasive MRSA infection among dialysis patients was 45.2 cases per 1,000 dialysis population, indicating a 100-fold higher risk than for the general population (Table). The rate varied by ABCs site, from 27.2 in California to 92.0 in Maryland. During July 2004–June 2006, approximately 70% of invasive MRSA infections among dialysis patients occurred in persons aged >50 years. Males and blacks accounted for 57% and 56%, respectively, of the total population of dialysis patients with these infections. The majority (86%) of the infections were bloodstream infections, identified via positive blood culture. Approximately 85% of dialysis patients had an invasive device or catheter in place at the time of infection, and approximately 90% required hospitalization. The in-hospital mortality rate for MRSA-related hospitalization was 17%.

Of the 126 MRSA isolates obtained from dialysis patients, 80% of the strains were of health-care origin, with USA100 representing 92% of the health-care strains and 74% of all isolates obtained. Community strains accounted for approximately 14% of the strains detected in dialysis patients, with USA300 accounting for 89% of the community strains and nearly 13% of all dialysis isolates. Six percent of the isolates either did not match existing USA strains within 80% or were classified as other non-USA strains. Antibiotic susceptibility results were reported for 113 MRSA isolates from dialysis patients. None of the isolates were resistant to vancomycin, daptomycin, or linezolid.

Reported by: *A Collins, MD, B Forrest, United States Renal Data System Coordinating Center, Minneapolis, Minnesota. RM Klevens, DDS, P Patel, MD, MJ Arduino, DrPH, G Fosheim, MPH, M Morrison, MPH, Div of Healthcare Quality Promotion, National Center for Preparedness, Detection, and Control of Infectious Diseases (proposed); CA Lucero, MD, EIS Officer, CDC.*

Editorial Note: Since the first renal dialysis was performed in 1943, substantial improvements have been made in dialysis technology and in the care of persons with end-stage renal disease (ESRD). At the same time, the number of dialysis patients has increased substantially. The dialysis population reached 335,963 at the end of 2004, triple the number from 1988 and up 16% since 2000 (*3*). Repeated hospitalizations

TABLE. Number and rate of invasive methicillin-resistant *Staphylococcus aureus* (MRSA) cases among dialysis patients, by state of surveillance area* — Active Bacterial Core surveillance system, 2005

State	No. of invasive MRSA cases among dialysis patients	No. of invasive MRSA cases among nondialysis patients	Dialysis population†	Rate of invasive MRSA cases per 1,000 dialysis population
California	109	827	4,008	27.2
Colorado	69	411	1,579	43.7
Connecticut	132	820	3,242	40.7
Georgia	226	939	4,250	53.2
Maryland	157	585	1,706	92.0
Minnesota	13	82	498	26.1
New York	35	272	895	39.1
Oregon	34	271	1,049	32.4
Tennessee	38	267	760	50.0
Total	**813**	**4,474**	**17,987**	**45.2**

* Surveillance areas include the entire state of Connecticut and 23 counties in eight other states (California, Colorado, Georgia, Maryland, Minnesota, New York, Oregon, and Tennessee).
† Number of dialysis patients in the selected surveillance area, based on United States Renal Data System Dialysis population count, as of December 31, 2004.

and surgeries and administration of prolonged courses of antimicrobial agents increase exposure to potential pathogens and create opportunities for antimicrobial resistance in this population. The rate of invasive MRSA infection described in this report (45.2 infections per 1,000 dialysis population) is higher than for any other known patient population and is 100 times higher than for the general population. Overall incidence of invasive MRSA in the general population ranges from 0.2 to 0.4 infections per 1,000 population (*2*).

Infections are the second most common cause of death in ESRD patients, accounting for nearly 14% of deaths (*3*). Approximately 70% of ESRD patients receive long-term dialysis treatment. Infections associated with vascular access are among the most serious complications of chronic dialysis. Data from the Dialysis Surveillance Network, reported through March 2005, indicate that the organisms most frequently associated with catheter-access–related bacteremias were coagulase-negative staphylococci (38%), *S. aureus* (29%), gram-negative bacilli (21%), and nonstaphylococcal gram-positive cocci, including enterococci (10%) (*5*). Dialysis patients with *S. aureus* bloodstream infections have costly and lengthy hospitalizations, frequently with substantial complications and hospital readmission (*6*).

Persons receiving hemodialysis are especially vulnerable to vascular-access infections because they require vascular access for prolonged periods and undergo frequent puncture of their vascular-access site. Furthermore, patients colonized with MRSA can serve as a reservoir for transmission in health-care settings. The primary risk factor for bacterial infections among dialysis patients is vascular-access type. Risk is highest for catheters, intermediate for grafts, and lowest for native arteriovenous fistulas (*5*). Despite higher rates of bacteremia among patients with catheters, the percentage of U.S. dialysis patients with an indwelling hemodialysis catheter increased substantially from 1995 to 2002 (*7*). The most basic strategy to prevent catheter-related bacteremias, including invasive MRSA infections among hemodialysis patients, is minimizing the use of catheters for long-term vascular access (*1*).

Antimicrobial therapy for hemodialysis-associated infections is one of the factors increasing the prevalence of antimicrobial resistance. MRSA strains of health-care origin, such as USA100, are typically multidrug resistant. During 1995–2002, the percentage of dialysis centers treating one or more patients with MRSA increased from 40% to 76% (*7*). In addition, in the United States, during 1997–2000, five of the first six patients reported with vancomycin-intermediate *S. aureus* had received dialysis (*8*), and the first patient reported to be infected with vancomycin-resistant *S. aureus* was a hemodialysis patient (*9*).

Health-care providers should follow published guidelines for judicious use of antimicrobials, particularly vancomycin, to reduce selection for antimicrobial-resistant pathogens (*1*). Recommendations for the prevention of antimicrobial resistance are available from CDC's 12-step Campaign to Prevent Antimicrobial Resistance Among Dialysis Patients (*10*). In addition, a resource on the prevention of infections and patient-to-patient transmission of infections in dialysis settings is CDC's *Recommendations for Preventing Transmission of Infections Among Chronic Hemodialysis Patients* (*1*).

Notice to Readers

Ground Water Awareness Week, March 11–17, 2007

Approximately 40%–45% of the U.S. population depends on ground water for its drinking water supply (*1–3*). Each year, the National Ground Water Association (NGWA) sponsors Ground Water Awareness Week to highlight ground water as a valuable resource and to emphasize the importance of private well maintenance and water testing (*4*).

Ground water quality can be affected by local land uses, geologic factors, and integrity of water wells. Possible contaminants include disease-causing microorganisms, natural contaminants, and manufactured pollutants. Thirty waterborne-disease outbreaks affecting approximately 2,760 persons were reported to CDC during 2003–2004; seven outbreaks (23%) were associated with improperly treated or untreated ground water, two of which involved private wells (*5*).

Private domestic wells are not regulated by the U.S. Environmental Protection Agency, and private well owners are responsible for ensuring the water is safe. Routine annual well-maintenance checks by a qualified water-well systems contractor are recommended to help prevent water-quality problems. Routine annual water testing for coliform bacteria, nitrates and nitrites, and any contaminants of local concern also is recommended. NGWA suggests that water testing also might be considered if 1) a change in the taste, odor, or appearance of the well water occurs or if well repairs are required; 2) family members or houseguests have recurrent incidents of gastrointestinal illness; 3) an infant is living in the home; 4) a person would like to monitor the efficiency and performance of home water-treatment equipment; or 5) a person is buying a home and would like to assess the safety and quality of the existing water supply (*6–9*).

Additional information regarding well maintenance, water testing, and National Ground Water Awareness Week is available at http://www.wellowner.org and http://www.cdc.gov/ncidod/dpd/healthywater/privatewell.htm.

—: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts.

* Incidence data for reporting years 2006 and 2007 are provisional, whereas data for 2002, 2003, 2004, and 2005 are finalized.

† Calculated by summing the incidence counts for the current week, the 2 weeks preceding the current week, and the 2 weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.

§ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenza-associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.

¶ Includes both neuroinvasive and non-neuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed) (ArboNET Surveillance). Data for West Nile virus are available in Table II.

** Data for *H. influenzae* (all ages, all serotypes) are available in Table II.

†† Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention (proposed). Implementation of HIV reporting influences the number of cases reported. Updates of pediatric HIV data have been temporarily suspended until upgrading of the national HIV/AIDS surveillance data management system is completed. Data for HIV/AIDS, when available, are displayed in Table IV, which appears quarterly.

§§ Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases (proposed). A total of 26 cases were reported for the 2006–07 flu season.

¶¶ No measles cases were reported for the current week.

*** Data for meningococcal disease (all serogroups) are available in Table II.

††† No rubella cases were reported for the current week.

§§§ Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed).

C.N.M.I.: Commonwealth of Northern Mariana Islands.
U: Unavailable. —: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.
* Incidence data for reporting years 2006 and 2007 are provisional.
† Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed) (ArboNET Surveillance).
§ Data for California serogroup, eastern equine, Powassan, St. Louis, and western equine diseases are available in Table I.
¶ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenza-associated pediatric mortality, and in 2004 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
** Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

Total	12,722**	8,610	2,864	735	247	262	867

U: Unavailable. —:No reported cases.

* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

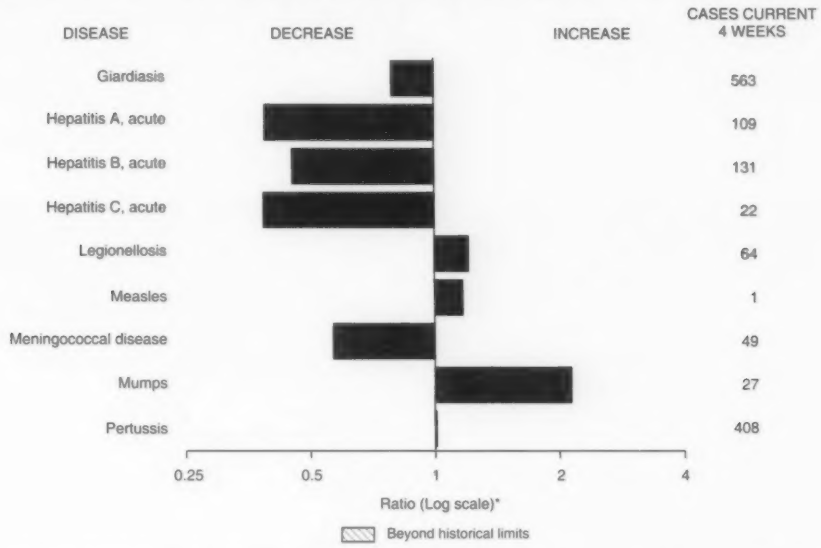
† Pneumonia and influenza.

§ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶ Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.

** Total includes unknown ages.

FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals March 3, 2007, with historical data



* Ratio of current 4-week total to mean of 15 4-week totals (from previous, comparable, and subsequent 4-week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's Internet server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to *www.mmwrq@cdc.gov*.

All material in the *MMWR* Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to *MMWR* readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in *MMWR* were current as of the date of publication.
